

LOCKSET

ChainLock × *TemporalLock* × *GodLock*

LS-WP-0.1 9 September 2026 Author: Aziel Eliab / GodLock.AZ Status: local specification. Cite, do not impersonate the public ledger. Command: `chainlock.py seal` · Rule: one member fail fails the set

0. Sentence

Public verification of local memory is a three-body lattice, not a single hash. If one member fails, the set is false.

1. Claim

ChainLock holds tips. TemporalLock writes a neutral receipt. GodLock is the public cite. Those three must agree on one canonical object called LOCKSET. Agreement is mechanical: hashes match, tips have not drifted, both companion blocks exist.

This is the same instinct as GodLock citation-over-reanswer and as TemporalLock's refusal to narrate. LOCKSET just binds them so a reader cannot treat a local vault as "verified publicly" when the public cite is missing.

2. What it is not

- Not a GodLock write path. `seal` cites `https://godlock.uk`. The operator posts the lockset SHA-256.
- Not a TemporalLock rewrite. The receipt is a new file under `vault/receipts/`. Old receipts stay.
- Not encryption. LOCKSET does not seal privileged plaintext. It seals hashes of public-plane cards.
- Not a live QNM membership proof.

3. Members

Each live chain contributes:

- `c` chain name
- `id` tip stamp id
- `h` tip stamp_sha256
- `fh` SHA-256 of the clipped tip fact

Chains with no stamps are omitted. Empty vault cannot seal.

Temporal block:

- `kind`: TemporalLock
- `ts`: UTC
- `note`: "Neutral receipt. No narrative. No authority."
- `n`: member count

GodLock block:

- `node`: godlock

- url: `https://godlock.uk`
- cite: `public-verify`
- pull: `false`
- isolate: `true`

`lockset_sha256` is SHA-256 of the canonical JSON of those fields with the hash field omitted. The file `vault/receipts/LOCKSET.json` is the live set. A copy `vault/receipts/TL-<prefix>.json` is the TemporalLock receipt. A mesh stamp records the cite. After that mesh append, members are recomputed so the mesh tip is inside the set.

4. Verify

`chainlock.py verify` now returns `lattice` as well as `per-chain ok`.

Fail-closed conditions:

- any chain prev break, body-hash miss, stamp-hash miss, or SSH-fail
- LOCKSET file missing after a seal has been made (sealed vaults only; unsealed vaults verify chains alone)
- LOCKSET file unreadable
- stored `lockset_sha256` $\neq$ recomputed hash
- any stored tip `h` $\neq$ live tip `h` (tip drift)
- missing `godlock` block
- missing `temporal` block

Any one of those sets `ok: false` and `lattice: false`. Breaks are listed. History is not rewritten.

5. Drift

Interact, append, library-sync, mesh-cite, and compact all move tips. That is correct. The set is a snapshot. After material change, seal again. An old TL receipt remains as history. The live file is always `LOCKSET.json`.

6. Public path

Post the lockset SHA-256 on GodLock. Do not upload stamp bodies. Citation over reanswer. 777s-class anti-poison on the public node is unchanged.

A reader who has the vault and the public cite can check: recompute the lockset hash, confirm the GodLock entry names that hash, confirm live tips still match. If GodLock is dark, the local receipt still exists. That is site-fail resilience, not public verification.

7. Cap

Seal cites. It does not write the GodLock ledger from this runtime. Do not print legal name or home on the receipt.
